

The Sausage Sizzle

Annotation

Jan can use a two way table to evaluate claims involving two stage chance situations, that have been made. She can see why a claim might not be valid and can suggest suitable improvements that could be made.

Problem: The Sausage Sizzle

The teacher gives this example and task:

A group of parents are running a fundraising sausage sizzle at a school sports event. To help plan for further sizzles, they record the sales in the table below.

	Plain Sausage	Sausage with Onion
Players	43	11
Spectators	58	86

The parents made the following claims from these results:

- 1. The probability that a customer is a player who wants onions is $1/18$.*
- 2. For an event that has 108 players, we can expect to sell 22 sausages with onions.*
- 3. If 400 sausages are sold in the next event, we can expect to have sold 204 plain (no onions) sausages.*

Evaluate the claims made by the parents.

Student Response

Sausages

$$\begin{array}{r} 1. \quad 43 \\ 58 \\ 11 \\ \hline 86 \\ 198 \\ \hline \end{array}$$

Probability player and onion

$$= \frac{11}{198} = \frac{11}{11 \times 18} = \frac{1}{18}$$

✓ Yes this claim can be made

2. ? Do all players buy a sausage?
What about spectators?

$$\text{Players } 43 + 11 = 54$$

$$54 \times (2) = 108$$

$$(2) \times 11 = 22 \quad \checkmark \text{ that bit is OK}$$

Change the claim:

If 108 players at an event buy a sausage then we expect 22 of those players to choose onions.

$$\begin{array}{r} 3. \quad 43 \\ 58 \\ \hline 101 \end{array}$$

$$\frac{101}{198} \times 400 = 204 \text{ (odp)}$$

✓ Yes this claim can be made

Teacher: What can you tell me about these claims?

Jan: I checked through all the numbers and could see that the parents didn't make any mistakes calculating probabilities.

Teacher: But you were not happy with the second claim.

Jan: No. The wording was a bit rough. Not every player buys a sausage, so it should only be about the players who do. Also, the spectators weren't considered so the claim should be clear that it's not about them.

Teacher: Tell me about your calculations.

Jan: For the first one, the probability would be the 11 from players who had onions out of the total number of sausages sold. So that comes to 198. I got $11/198$, but they got $1/18$, so I looked at the fraction and saw that it simplified and so their answer was the same as mine.

Then for the next one, I looked at how many players bought sausages, 54. Then because twice that is

108, we are kind of just looking at doubling the sales. After I fixed up the claim of course.

Teacher: And the last claim. Can you explain your working.

Jan: The total number of plain sausages sold was 101 and I already calculated total sausages to be 198 so I just used that number again. Then that fraction gives me the probability of selling a plain sausage. So if I times that by 400 I get the expected number of plain ones that will sell.
